Class 8

Challana Tea

#Import the dataset

Before we can begin our analysis we first have to download and import the data correctly into our R session. Use read.csv()

```
wisc.df <- read.csv("Wisconsincancer.csv",row.names=1)
head(wisc.df)
```

```
         diagnosis radius_mean texture_mean perimeter_mean area_mean
842302           M       17.99        10.38         122.80    1001.0
842517           M       20.57        17.77         132.90    1326.0

843786                   0.12440 NA
```

Q1. How many samples and variables are in this dataset?

```r
nrow(wisc.df)
```

```
[1] 569
```

```r
ncol(wisc.df)
```

```
[1] 32
```

Q2. How many M and B samples are there?

```r
sum(wisc.df$diagnosis=="M")
```

```
[1] 212
```

```r
sum(wisc.df$diagnosis=="B")
```

```
[1] 357
```

```r
table(wisc.df$diagnosis)
```

```

  B   M 
357 212 
```

Q3. How many variables/features in the data are suffixed with _mean?

```r
length(grep("_mean",colnames(wisc.df)))
```

```
[1] 10
```

Q. What features are "mean" values (or have "mean" in their name)

```r
(grep("_mean",colnames(wisc.df), value=TRUE))
```

```
 [1] "radius_mean"            "texture_mean"           "perimeter_mean"        
 [4] "area_mean"              "smoothness_mean"        "compactness_mean"      
 [7] "concavity_mean"         "concave.points_mean"    "symmetry_mean"         
[10] "fractal_dimension_mean"
```

I need to remove the first diagnosis column from the data before doing any analysis. I will store it for later as a factor

```r
# We can use -1 here to remove the first column
wisc.data <- wisc.df[,-1]
diagnosis <- as.factor(wisc.df$diagnosis)
```

2. Principal Component Analysis

The main PCA function in base R is called `prcom()`.

Before doing anything like PCA, it is important to check if the data need to be scaled before performing PCA. Recall two common reasons for scaling data include:

- The input variables use different units of measurement.
- The input variables have significantly different variances.

Looks like we need to scale by setting `scale=TRUE` in our `prcomp()` function call.

```r
round(apply(wisc.data, 2, sd), 2)
```

```
            radius_mean            texture_mean          perimeter_mean 
                   3.52                    4.30                   24.30

```

> Q4. From your results, what proportion of the original variance is captured by the first principal components (PC1)?

44.27

> Q5. How many principal components (PCs) are required to describe at least 70% of the original variance in the data?

PC3

Q6. How many principal components (PCs) are required to describe at least 90% of the original variance in the data?

PC7

```
attributes(wisc.pr)
```

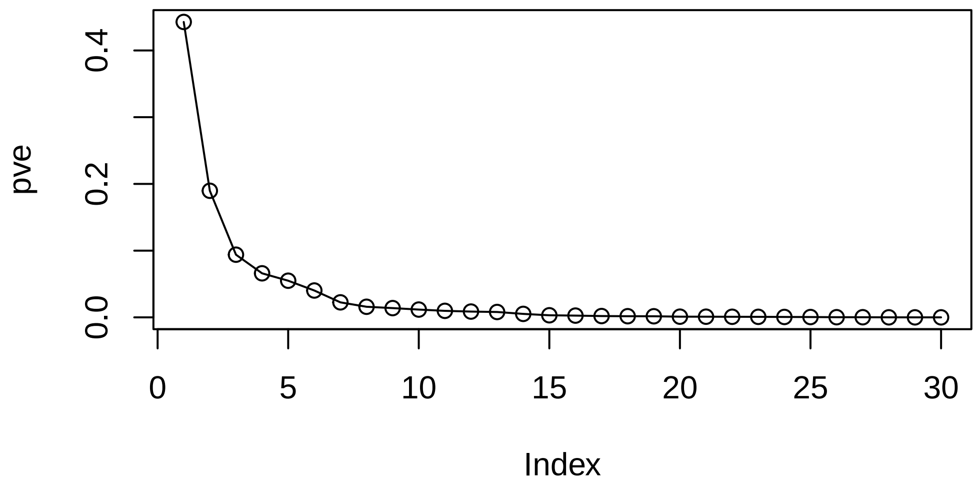
```
$names
[1] "sdev"     "rotation" "center"   "scale"    "x"

$class
[1] "prcomp"
```

Make a little scree plot

```
pr.var <- wisc.pr$sdev^2
#Proportion of variance
pve <- pr.var/sum(pr.var)

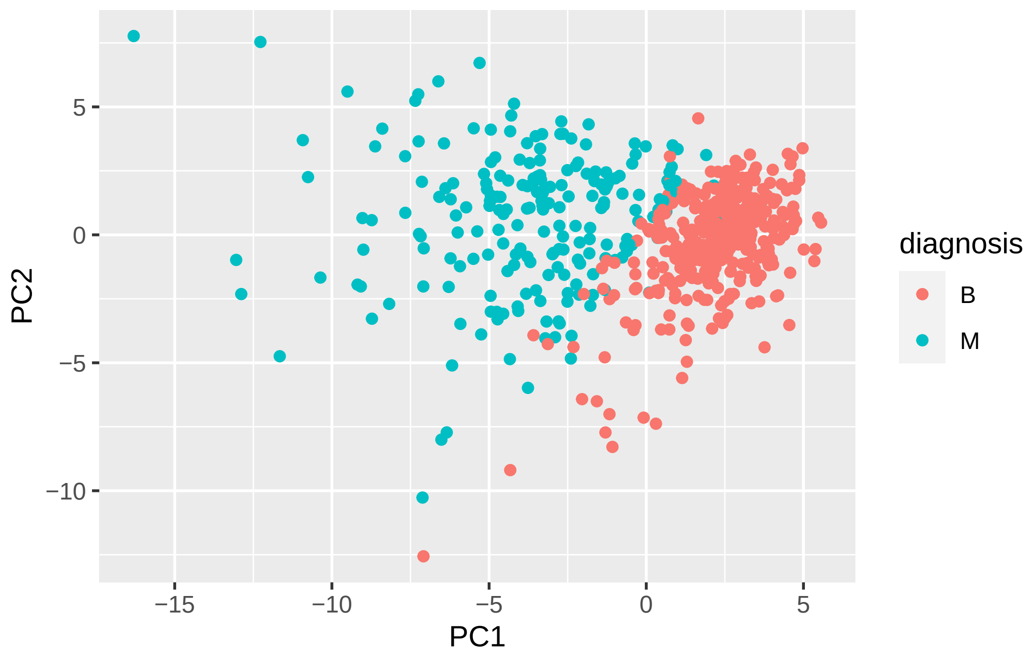
plot(pve, typ="o")
```



PC plot

```
library(ggplot2)
pc <- as.data.frame(wisc.pr$x)

ggplot(pc) +
  aes(x=PC1,y=PC2,col=diagnosis) +
  geom_point()
```



Hierarchical clustering

We can try clustering the original data with `hclust()` or `kmeans()`. First we will scale the data just like we did for PCA

```
data.scaled <- scale(wisc.data)
head(apply(data.scaled,2,sd))
```

```
    radius_mean      texture_mean    perimeter_mean         area_mean 
              1                 1                 1                 1 
smoothness_mean compactness_mean 
              1                 1 
```

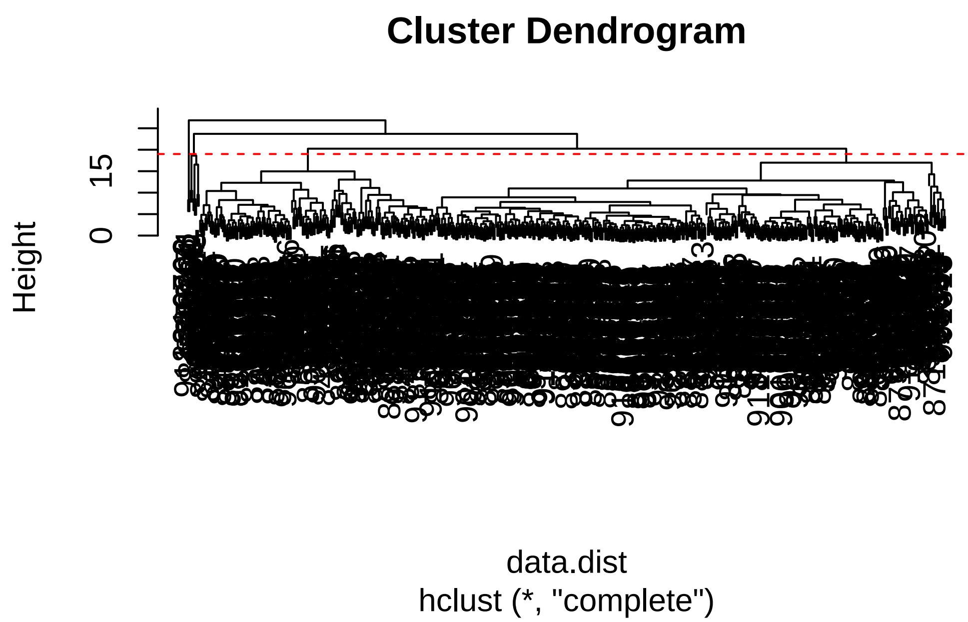
```
data.dist <- dist(data.scaled)
wisc.hclust <- hclust(data.dist, method = "complete")
wisc.hclust
```

```
Call:
hclust(d = data.dist, method = "complete")

Cluster method   : complete
Distance         : euclidean
Number of objects: 569
```

Plot the dendogram

```
plot(wisc.hclust)
abline(h=19, col="red", lty=2)
```



To get a cluster membership vector I will use the `cutree()` function and "cut" into 4 or so grps or clusters.

> Q10. Using the plot() and abline() functions, what is the height at which the clustering model has 4 clusters?

h = 19

```
grps <- cutree(wisc.hclust, h=19)
table(grps)
```

```
grps
  1   2   3   4 
177   7 383   2 
```

I can also use the `table()` to cross tabulate…

```
table(diagnosis)
```

```
diagnosis
  B   M 
357 212 
```

```
table(grps,diagnosis)
```

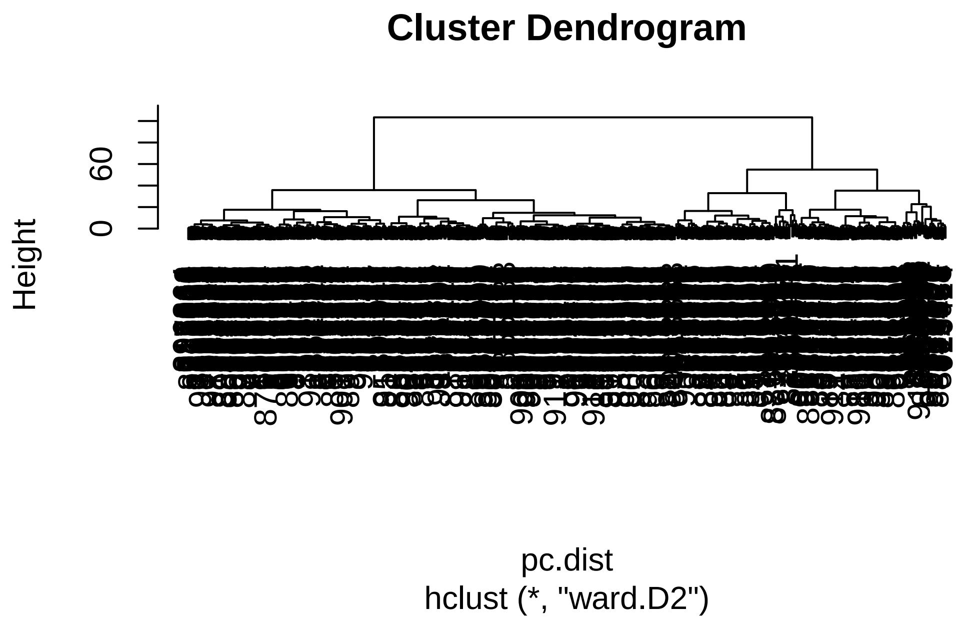
```
    diagnosis
grps   B   M
   1  12 165
   2   2   5
   3 343  40
   4   0   2
```

Clustering on PCA Results

I can cluster in PC-space and use as many or as few PCs as I want.

To start with I will use 3 PCs, that is I will cluster along PC1, PC2, and PC3.

```
pc.dist <- dist(wisc.pr$x[,1:3])
wisc.pr.hclust <- hclust(pc.dist, method="ward.D2")
plot(wisc.pr.hclust)
```



This looks nicer than the previous clustering result. Find the two major clusters with the `cutree()` function

```
grps <- cutree(wisc.pr.hclust, k=2)
table(grps)
```

```
grps
  1   2
203 366
```

```
table(grps, diagnosis)
```

```
    diagnosis
grps   B   M
   1  24 179
   2 333  33
```

We could calculate accuracy - the proportion of samples correct if we take cluster 1 to represent all M and cluster 2 to represent all B.

```r
(179+333)/nrow(wisc.data)
```

```
[1] 0.8998243
```

Prediction

```r
url <- "https://tinyurl.com/new-samples-CSV"
new <- read.csv(url)
npc <- predict(wisc.pr, newdata=new)
npc
```

```
           PC1       PC2        PC3        PC4       PC5        PC6        PC7

Q16. Which of these new patients should we prioritize for follow up based on your results?

Patient 2 should be prioritized.
